## QUESTION 2

PAC.

Given Data.

- Request (Number of elevator Requests).
- Rfloor (Requested floor)

Required Results

- Real-time messages
  1. Moving up
  2. Moving down
  3. doors opening

Processing Required

- Initialise (current floor) Cfloor to zero.
- Use for loop from 1 to Requests
- Input Rfloor
- check if Rfloor is greater lesser or equals to cfloor
- if greater then print Moving up, if lesser then Moving down otherwise.
- print doors opening.

Alternative Solution.

- Use while loop instead of for loop.
- for this use another variable, and initialise this to 1 before loop starts
- Use this condition for loop.  
~~while~~ Index  $\leq$  Requests.
- Increment index inside the loop after each Request is processed.
